# CHEMICAL ABSTRACTS

Vol. 43 DECEMBER 25, 1949 No. 24

## III. FORMULA INDEX

### KEY

n using this index the following should be ne in mind:

. The Formula Index does not replace any t of the Subject Index. Unnamed, incomely described compounds can sometimes be xed *specifically* in the Formula Index only, there are cross references from the Formula ex to the Subject Index for the simpler and mmoner compounds; otherwise compounds are pletely indexed both by formulas and by nes.

**Inorganic as well as organic compounds** e been entered.

**Entries under their own formulas** are de for all strictly inorganic and strictly orne compounds, both addition compounds and e reaction derivatives (this includes esters, razones, oximes, picrates, semicarbazones, ). Inorganic salts of organic acids and inorne addition compounds of organic compounds ydrohalides, chloroplatinates, perchlorates, lfates, etc.) are not given separate entries but e indicated in modifying phrases under the rmulas of the compounds from which they are rived (under the acid in the case of a salt). alts of formic, acetic, and oxalic acids are exptions; these are entered as such.

4. **The arrangement of symbols in formulas** alphabetical except that in carbon compounds always comes first, followed immediately by H hydrogen is also present.

**The arrangement of formulas** is also abetical except that the number of atoms of ny specific kind influences the order of compounds; e.g., all formulas with C (one carbon tom only) come before those with $C_2$, thus: $CCl_2O$, $CCl_4$, $CHCl_3$, CHN, CHNO, $CH_2Br_2$, $CH_4O$, $CH_3Cl$, CO, $C_2Ca$, $C_2H_4O_2$.

6. **The arrangement of entries under any heading** is alphabetical according to the preferred names of the isomers.

7. **Entries consist of** (*a*) the formula (in boldface type), (*b*) the name as it has been entered in the Subject Index (in light-face Roman type; *it should be noted particularly that the part of the entry in this type is the exact equivalent of the formula given*), (*c*) occasionally a modifying phrase or word such as "*Ca salt*" or "*di- HCl*" (in italics, different type being used to set off that part of a compound being indexed which is not represented in the formula used; see ¶3 above), (*d*) the column reference, and (*e*) the fraction of the column in ninths (indicated by an italic letter) in which the compound will be found.

8. **Cross references** are to the Subject Index.

9. **Water of hydration** is not made a part of the formulas indexed but is often given in light-face type following the formulas.

10. **Polymers** having different names and recognized as different substances, e.g., acetaldehyde and paraldehyde, are all entered under their accepted formulas. But a definite compound for which different polymeric formulas are in use is entered under the simplest formula.

11. **A straight line,** thus—, used under some headings to avoid repetition of names, always stands for the name of the "index compound," i.e., that part of the preceding name which comes before the comma.

12. "P" before a page number indicates that the abstract is of a **patent.**

13. The **names beryllium** (Be), **columbium** (Cb), and **hafnium** (Hf) are given preference over glucinum (Gl), niobium (Nb) and celtium (Ct), respectively, for these elements.

14. For **deuterium** ($H^2$) and **tritium** ($H^3$),

respectively, the symbols D and T are used. These are placed alphabetically in formulas, the exception in arrangement made for H not being extended to include these isotopes.

*The Key to a formula index is necessarily lengthy. It would not be correct to conclude from this that this index is difficult to use. Experience is to the contrary.*

## INTRODUCTION

**General purpose and policy.** The location of chemical compounds in an index by names is at times uncertain because names vary and in the case of complex compounds may be difficult to ascertain. New compounds are constantly being prepared, which, if named at all, may receive more than one name that is justified from one point of view or another, and the possibilities of incorrect naming are considerable. Since the kinds and number of component atoms of a chemical compound are unvarying characteristics the supplementary Formula Index to *Chemical Abstracts* is published for the purpose of eliminating this element of uncertainty in the Subject Index. The Subject Index is in no way altered on account of the Formula Index. In the Subject Index related compounds are *grouped* rather effectively and to good use by the present system of indexing on the basis of "parent compounds" or, more accurately, "index compounds"; in the Formula Index the certain location of *individual* compounds is the primary consideration. The Subject Index is more convenient to use in some respects, and it frequently contains more information in the form of modifying phrases. The repetition of modifying phrases in the Formula Index beyond necessary brief expressions to indicate derivative has been avoided as unnecessary for the accomplishment of the real purpose of this index, as stated above. Isomerism is not indicated in the Formula Index in cases in which the names differ only in position numbers or letters, but it always is in the Subject Index when known. Ready reference to the Subject Index for the purpose of locating information regarding related compounds is made possible by the use in the Formula Index of names following the formulas written exactly as they appear in the former index (except for the indication of isomerism as above mentioned).

All new compounds and all compounds for which new information is given have been entered. Most of the compounds have been entered under their own formulas. Some departure from a policy of making separate formula entries for derivatives of all kinds is reasonable and accords with custom. The only departures in this index (see ¶3 of the Key) have been in classes of compounds the natures of which would be more than likely apparent to the investigator. The interest in a salt of a complex organic acid, for example, is likely to be mainly in the acid, and it is considered more valuable to have the record of it under the formula of the acid for the use of searchers looking up that acid.

In the case of unnamed organic compounds, where possible, the class, as acid, and melting or boiling point have been given.

Cross references to the Subject Index have been used for many simple inorganic compounds, for all minerals of definite composition, and for the organic compounds more commonly met with, in general, whenever it seemed likely that users of *Chemical Abstracts* would predominantly refer to the Subject Index.

**The System.** The system, as described in the Key, is with slight modifications, that worked out by Edwin A. Hill[1] and used by the Classification Division of the U.S. Patent Office. This system is preferred to the system of Richter's Lexikon because of its greater simplicity and its applicability with equal fitness to inorganic and to organic compounds.
